

PRAYCG NUPI v0.1 Report

Narrative Update Polarity Index: Arrival, Contact, and Field of Dreams

Document status: exploratory analysis report. NUPI is a proxy-level polarity classifier, not a literal thermodynamic, clinical, moral, or consciousness measure.

Executive conclusion

NUPI v0.1 evaluates narrative-update polarity along two axes: Accommodative Load Index (ALI) and Resolutive Recovery Index (RDI). ALI estimates how much a story appears to demand model expansion or semantic work. RDI estimates whether the after-state shows regulatory recovery, reflective semantic echo, and self-reported afterglow. NUPI is computed as RDI minus ALI only when an after-state physiology layer is available.

Bottom line: Contact is high-load-with-recovery, Field of Dreams is resolutive-recovery, and Arrival is recognition-dominant but polarity-unresolved because it lacks a PRAYCG2.0-style Baseline2 layer and did not pass the strict gates.

Run-level NUPI summary

run	ALI_accommodative_load	RDI_resolutive_recovery	RDI_afterstate_proxy	NUPI	polarity_class
Arrival	0.382		0.911		POLARITY_UNRESOLVED_NO_BASELINE2
Contact	0.658	0.820	0.807	0.162	HIGH_LOAD_WITH_RECOVERY
Field	0.335	0.711	0.835	0.376	RESOLUTIVE_RECOVERY

Formal definitions

ALI = mean(semantic intensity, Target specificity, complexity perturbation, TTI score, primary endpoint pass score).

RDI = mean(Baseline2 regulation, Baseline2 semantic echo, EET afterstate echo, self-report echo).

NUPI = RDI - ALI. Positive values imply recovery tilt; negative values imply load tilt. If no Baseline2 or comparable after-state physiology exists, NUPI is not graded.

Run interpretation

Arrival

Arrival remains a recognition-dominant/familiar schema-reactivation case. It shows Target-dominant CII and positive self-report, but strict BIT/A-MRED-style endpoints are negative and there is no final reflective Baseline2 physiology layer. NUPI therefore refuses to force a polarity classification.

Contact

Contact has the strongest semantic intensity and Target specificity across the three runs. It also shows strong Baseline2 regulatory recovery. The NUPI result therefore contradicts an overly simple metabolic-crater story: Contact appears to be a high-load, high-recovery update profile.

Field of Dreams

Field of Dreams is lower-amplitude than Contact in immediate semantic intensity, but stronger in reflective afterglow, Target echo, and Baseline2 recovery. NUPI classifies it as a resolute-recovery candidate: meaning as closure/regulatory dividend rather than meaning as peak shock.

Raw component inputs

run	target_CII_mean	target_specific_CII_mean	target_MMR_mean	target_ENC_mean	tti_global	b2_regulation_score	b2_semantic_echo_score	eet_baseline2_max	eet_afterstate_max
Arrival	0.304	0.299	0.432	0.187	0.533				0.976
Contact	0.893	0.868	1.108	1.009	0.745	1.000	0.667	0.830	0.957
Field	0.063	0.053	0.396	0.210	0.568	0.565	0.609	0.499	0.925

Boundaries and falsifiers

NUPI is exploratory. It becomes stronger only when anchors are frame-verified, ALS timing passes across branches, full StimulusFingerprint/CET-R regressors are available, and artifact/EOG/EMG controls survive. NUPI weakens if Control or Override show the same after-state profile, if residual stimulus regressors explain the effect, if Baseline2 is contaminated by report burden or fatigue, or if self-report contradicts the intended state.
