

Framework Integration Register v0.5

NUPI - Narrative Update Polarity Index

Document status: framework update register. This addendum formalizes NUPI as a secondary/exploratory interpretive layer inside PRAYCG/Topo-OSM. It does not replace A-MRED as the suggested primary endpoint.

Core theory

Narratives may differ not only in intensity, but in update polarity. Some meanings impose accommodative load: the system must expand, destabilize, or rebuild its predictive model. Other meanings produce resolute recovery: the system closes an open loop and recovers regulatory capacity. NUPI estimates this polarity using available PRAYCG outputs.

Formula

ALI = mean(semantic intensity, Target specificity, complexity perturbation, TTI, primary endpoint pass score).

RDI = mean(Baseline2 regulation, Baseline2 semantic echo, EET afterstate echo, self-report echo).

NUPI = RDI - ALI.

Module placement

Updated module tier map

Tier	Modules	Role
Primary recommended	Timing/QC + CET-R + artifact/confound gates -> A-MRED	Confirmatory candidate path
Secondary summaries	NIP/BIT/CII/IAQ, TTI, NUPI	Summarize immersion, extraction, and update polarity
Exploratory convergence	KHT-topo, NAST, EET, MRED-ITP/ACG/OCU, OCM/RSM/CVB/Squint	Mechanistic interpretation and falsification support

Claim boundary

NUPI does not measure heat, energy expenditure, ATP consumption, literal entropy, clinical restoration, or moral value. It classifies the shape of available proxy evidence. The proper claim is: PRAYCG may distinguish different narrative-update profiles under controlled conditions.
